Deep Generative Models

Lecture 3

Roman Isachenko

Autumn, 2022

Recap of previous lecture

MLE problem for autoregressive model

$$m{ heta}^* = rg \max_{m{ heta}} p(\mathbf{X}|m{ heta}) = rg \max_{m{ heta}} \sum_{i=1}^n \sum_{j=1}^m \log p(x_{ij}|\mathbf{x}_{i,1:j-1},m{ heta}).$$

Sampling

$$\hat{x}_1 \sim p(x_1|\boldsymbol{\theta}), \quad \hat{x}_2 \sim p(x_2|\hat{x}_1,\boldsymbol{\theta}), \quad \dots, \quad \hat{x}_m \sim p(x_m|\hat{\mathbf{x}}_{1:m-1},\boldsymbol{\theta})$$

New generated object is $\hat{\mathbf{x}} = (\hat{x}_1, \hat{x}_2, \dots, \hat{x}_m)$.

Masking helps to make neural network autoregressive.

- ► MADE masked autoencoder (MLP).
- WaveNet masked 1D convolutions.
- PixelCNN masked 2D convolutions.

Recap of previous lecture

Posterior distribution

$$p(\theta|\mathbf{X}) = \frac{p(\mathbf{X}|\theta)p(\theta)}{p(\mathbf{X})} = \frac{p(\mathbf{X}|\theta)p(\theta)}{\int p(\mathbf{X}|\theta)p(\theta)d\theta}$$

Bayesian inference

$$p(\mathbf{x}|\mathbf{X}) = \int p(\mathbf{x}|\theta)p(\theta|\mathbf{X})d\theta$$

Maximum a posteriori (MAP) estimation

$$\boldsymbol{\theta}^* = \argmax_{\boldsymbol{\theta}} p(\boldsymbol{\theta}|\mathbf{X}) = \argmax_{\boldsymbol{\theta}} \left(\log p(\mathbf{X}|\boldsymbol{\theta}) + \log p(\boldsymbol{\theta})\right)$$

MAP inference

$$p(\mathbf{x}|\mathbf{X}) = \int p(\mathbf{x}|\theta)p(\theta|\mathbf{X})d\theta \approx p(\mathbf{x}|\theta^*).$$

Recap of previous lecture

Latent variable models (LVM)

$$p(\mathbf{x}|\boldsymbol{\theta}) = \int p(\mathbf{x}, \mathbf{z}|\boldsymbol{\theta}) d\mathbf{z} = \int p(\mathbf{x}|\mathbf{z}, \boldsymbol{\theta}) p(\mathbf{z}) d\mathbf{z}.$$

MLE problem for LVM

$$egin{aligned} m{ heta}^* &= rg\max_{m{ heta}} \log p(\mathbf{X}|m{ heta}) = rg\max_{m{ heta}} \sum_{i=1}^n \log p(\mathbf{x}_i|m{ heta}) = \ &= rg\max_{m{ heta}} \log \sum_{i=1}^n \int p(\mathbf{x}_i|\mathbf{z}_i,m{ heta}) p(\mathbf{z}_i) d\mathbf{z}_i. \end{aligned}$$

Naive Monte-Carlo estimation

$$p(\mathbf{x}|\boldsymbol{\theta}) = \int p(\mathbf{x}|\mathbf{z}, \boldsymbol{\theta}) p(\mathbf{z}) d\mathbf{z} = \mathbb{E}_{p(\mathbf{z})} p(\mathbf{x}|\mathbf{z}, \boldsymbol{\theta}) pprox rac{1}{K} \sum_{k=1}^{K} p(\mathbf{x}|\mathbf{z}_k, \boldsymbol{\theta}),$$
 where $\mathbf{z}_k \sim p(\mathbf{z})$.

Variational lower bound (ELBO)

Derivation 1 (inequality)

$$\log p(\mathbf{x}|\boldsymbol{\theta}) = \log \int p(\mathbf{x}, \mathbf{z}|\boldsymbol{\theta}) d\mathbf{z} \geq \mathbb{E}_q \log \frac{p(\mathbf{x}, \mathbf{z}|\boldsymbol{\theta})}{q(\mathbf{z})} = \mathcal{L}(q, \boldsymbol{\theta})$$

Derivation 2 (equality)

$$\mathcal{L}(q, \theta) = \int q(\mathbf{z}) \log \frac{p(\mathbf{x}, \mathbf{z}|\theta)}{q(\mathbf{z})} d\mathbf{z} = \int q(\mathbf{z}) \log \frac{p(\mathbf{z}|\mathbf{x}, \theta)p(\mathbf{x}|\theta)}{q(\mathbf{z})} d\mathbf{z} =$$

$$= \log p(\mathbf{x}|\theta) - KL(q(\mathbf{z})||p(\mathbf{z}|\mathbf{x}, \theta))$$

Variational decomposition

$$\log p(\mathbf{x}|\boldsymbol{\theta}) = \mathcal{L}(q,\boldsymbol{\theta}) + KL(q(\mathbf{z})||p(\mathbf{z}|\mathbf{x},\boldsymbol{\theta})) \geq \mathcal{L}(q,\boldsymbol{\theta}).$$

Outline

1. EM-algorithm, amortized inference

2. ELBO gradients, reparametrization trick

3. Variational autoencoder (VAE)

Outline

- 1. EM-algorithm, amortized inference
- ELBO gradients, reparametrization trick
- Variational autoencoder (VAE)

Variational lower bound (ELBO)

$$\mathcal{L}(q, \theta) = \int q(\mathbf{z}) \log \frac{p(\mathbf{x}, \mathbf{z}|\theta)}{q(\mathbf{z})} d\mathbf{z} =$$

$$= \int q(\mathbf{z}) \log p(\mathbf{x}|\mathbf{z}, \theta) d\mathbf{z} + \int q(\mathbf{z}) \log \frac{p(\mathbf{z})}{q(\mathbf{z})} d\mathbf{z}$$

$$= \mathbb{E}_q \log p(\mathbf{x}|\mathbf{z}, \theta) - KL(q(\mathbf{z})||p(\mathbf{z}))$$

Log-likelihood decomposition

$$\log p(\mathbf{x}|\boldsymbol{\theta}) = \mathbb{E}_q \log p(\mathbf{x}|\mathbf{z},\boldsymbol{\theta}) - KL(q(\mathbf{z})||p(\mathbf{z})) + KL(q(\mathbf{z})||p(\mathbf{z}|\mathbf{x},\boldsymbol{\theta})).$$

▶ Instead of maximizing incomplete likelihood, maximize ELBO

$$\max_{\boldsymbol{\theta}} p(\mathbf{x}|\boldsymbol{\theta}) \rightarrow \max_{\boldsymbol{q},\boldsymbol{\theta}} \mathcal{L}(\boldsymbol{q},\boldsymbol{\theta})$$

► Maximization of ELBO by variational distribution q is equivalent to minimization of KL

$$\max_{q} \mathcal{L}(q, \theta) \equiv \min_{q} \mathit{KL}(q(\mathbf{z})||p(\mathbf{z}|\mathbf{x}, \theta)).$$

EM-algorithm

$$egin{aligned} \mathcal{L}(q, oldsymbol{ heta}) &= \mathbb{E}_q \log p(\mathbf{x}|\mathbf{z}, oldsymbol{ heta}) - \mathcal{K}\mathcal{L}(q(\mathbf{z})||p(\mathbf{z})) = \ &= \mathbb{E}_q \left[\log p(\mathbf{x}|\mathbf{z}, oldsymbol{ heta}) - \log rac{q(\mathbf{z})}{p(\mathbf{z})}
ight] d\mathbf{z}
ightarrow \max_{q, oldsymbol{ heta}}. \end{aligned}$$

Block-coordinate optimization

- lnitialize θ^* ;
- ► E-step

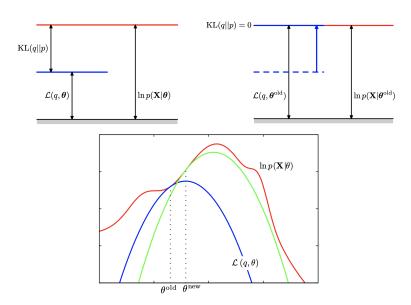

$$egin{aligned} q^*(\mathbf{z}) &= rg \max_q \mathcal{L}(q, oldsymbol{ heta}^*) = \ &= rg \min_q \mathit{KL}(q(\mathbf{z}) || \mathit{p}(\mathbf{z}|\mathbf{x}, oldsymbol{ heta}^*)) = \mathit{p}(\mathbf{z}|\mathbf{x}, oldsymbol{ heta}^*); \end{aligned}$$

M-step

$$\theta^* = \arg\max_{oldsymbol{ heta}} \mathcal{L}(q^*, oldsymbol{ heta});$$

Repeat E-step and M-step until convergence.

EM illustration

Amortized variational inference

E-step

$$q(\mathbf{z}) = rg \max_{q} \mathcal{L}(q, \boldsymbol{\theta}^*) = rg \min_{q} \mathit{KL}(q||p) = p(\mathbf{z}|\mathbf{x}, \boldsymbol{\theta}^*).$$

- ▶ $q(\mathbf{z})$ approximates true posterior distribution $p(\mathbf{z}|\mathbf{x}, \theta^*)$, that is why it is called **variational posterior**;
- \triangleright $p(\mathbf{z}|\mathbf{x}, \boldsymbol{\theta}^*)$ could be **intractable**;
- $ightharpoonup q(\mathbf{z})$ is different for each object \mathbf{x} .

Idea

Restrict a family of all possible distributions $q(\mathbf{z})$ to a parametric class $q(\mathbf{z}|\mathbf{x},\phi)$ conditioned on samples \mathbf{x} with parameters ϕ .

Variational Bayes

► E-step

$$\phi_k = \phi_{k-1} + \eta \nabla_{\phi} \mathcal{L}(\phi, \theta_{k-1})|_{\phi = \phi_{k-1}}$$

M-step

$$\boldsymbol{\theta}_k = \boldsymbol{\theta}_{k-1} + \eta \nabla_{\boldsymbol{\theta}} \mathcal{L}(\boldsymbol{\phi}_k, \boldsymbol{\theta})|_{\boldsymbol{\theta} = \boldsymbol{\theta}_{k-1}}$$

Variational EM-algorithm

ELBO

$$\log p(\mathbf{x}|\boldsymbol{\theta}) = \mathcal{L}(\boldsymbol{\phi},\boldsymbol{\theta}) + \mathit{KL}(q(\mathbf{z}|\mathbf{x},\boldsymbol{\phi})||p(\mathbf{z}|\mathbf{x},\boldsymbol{\theta})) \geq \mathcal{L}(\boldsymbol{\phi},\boldsymbol{\theta}).$$

► E-step

$$\phi_k = \phi_{k-1} + \eta \nabla_{\phi} \mathcal{L}(\phi, \theta_{k-1})|_{\phi = \phi_{k-1}},$$

where ϕ – parameters of variational posterior distribution $q(\mathbf{z}|\mathbf{x},\phi)$.

M-step

$$\theta_k = \theta_{k-1} + \eta \nabla_{\theta} \mathcal{L}(\phi_k, \theta)|_{\theta = \theta_{k-1}},$$

where θ – parameters of the generative distribution $p(\mathbf{x}|\mathbf{z}, \theta)$. Now all we have to do is to obtain two gradients $\nabla_{\phi}\mathcal{L}(\phi, \theta)$, $\nabla_{\theta}\mathcal{L}(\phi, \theta)$.

Challenge: Number of samples n could be huge (we heed to derive unbiased stochastic gradients).

Outline

- 1. EM-algorithm, amortized inference
- 2. ELBO gradients, reparametrization trick
- Variational autoencoder (VAE)

ELBO gradients, (M-step, $\nabla_{\theta} \mathcal{L}(\phi, \theta)$)

$$\mathcal{L}(\phi, oldsymbol{ heta}) = \mathbb{E}_{q(\mathbf{z}|\mathbf{x}, \phi)} \left[\log p(\mathbf{x}|\mathbf{z}, oldsymbol{ heta}) - \log rac{q(\mathbf{z}|\mathbf{x}, \phi)}{p(\mathbf{z})}
ight]
ightarrow \max_{\phi, heta}.$$

M-step: $\nabla_{\boldsymbol{\theta}} \mathcal{L}(\boldsymbol{\phi}, \boldsymbol{\theta})$

$$egin{aligned}
abla_{m{ heta}} \mathcal{L}(m{\phi}, m{ heta}) &= \int q(\mathbf{z}|\mathbf{x}, m{\phi})
abla_{m{ heta}} \log p(\mathbf{x}|\mathbf{z}, m{ heta}) d\mathbf{z} pprox \\ &pprox
abla_{m{ heta}} \log p(\mathbf{x}|\mathbf{z}^*, m{ heta}), \quad \mathbf{z}^* \sim q(\mathbf{z}|\mathbf{x}, m{\phi}). \end{aligned}$$

Naive Monte-Carlo estimation

$$p(\mathbf{x}|\boldsymbol{\theta}) = \int p(\mathbf{x}|\mathbf{z}, \boldsymbol{\theta}) p(\mathbf{z}) d\mathbf{z} = \mathbb{E}_{p(\mathbf{z})} p(\mathbf{x}|\mathbf{z}, \boldsymbol{\theta}) \approx \frac{1}{K} \sum_{k=1}^{K} p(\mathbf{x}|\mathbf{z}_k, \boldsymbol{\theta}),$$

where $\mathbf{z}_k \sim p(\mathbf{z})$.

The variational posterior $q(\mathbf{z}|\mathbf{x},\phi)$ assigns typically more probability mass in a smaller region than the prior $p(\mathbf{z})$. image credit: https://jmtomczak.github.io/blog/4/4_VAE.html

ELBO gradients, (E-step, $\nabla_{\phi}\mathcal{L}(\phi, \theta)$)

E-step: $\nabla_{\phi} \mathcal{L}(\phi, \theta)$

Difference from M-step: density function $q(\mathbf{z}|\mathbf{x}, \phi)$ depends on the parameters ϕ , it is impossible to use the Monte-Carlo estimation:

$$\nabla_{\phi} \mathcal{L}(\phi, \theta) = \nabla_{\phi} \int q(\mathbf{z}|\mathbf{x}, \phi) \left[\log p(\mathbf{x}|\mathbf{z}, \theta) - \log \frac{q(\mathbf{z}|\mathbf{x}, \phi)}{p(\mathbf{z})} \right] d\mathbf{z}$$

$$\neq \int q(\mathbf{z}|\mathbf{x}, \phi) \nabla_{\phi} \left[\log p(\mathbf{x}|\mathbf{z}, \theta) - \log \frac{q(\mathbf{z}|\mathbf{x}, \phi)}{p(\mathbf{z})} \right] d\mathbf{z}$$

Reparametrization trick (LOTUS trick)

- $r(x) = \mathcal{N}(x|0,1), y = \sigma \cdot x + \mu, p_Y(y|\theta) = \mathcal{N}(y|\mu,\sigma^2), \theta = [\mu,\sigma].$
- $\begin{array}{c} \boldsymbol{\mathsf{F}} & \boldsymbol{\mathsf{F}}$

$$\int r(\epsilon)
abla_{m{\phi}} f(g(\mathbf{x}, \epsilon, m{\phi})) d\epsilon pprox
abla_{m{\phi}} f(g(\mathbf{x}, \epsilon^*, m{\phi}))$$

ELBO gradient (E-step, $\nabla_{\phi} \mathcal{L}(\phi, \theta)$)

$$\nabla_{\phi} \mathcal{L}(\phi, \theta) = \nabla_{\phi} \int q(\mathbf{z}|\mathbf{x}, \phi) \log p(\mathbf{x}|\mathbf{z}, \theta) d\mathbf{z} - \nabla_{\phi} \mathsf{KL}(q(\mathbf{z}|\mathbf{x}, \phi)||p(\mathbf{z}))$$

$$= \int r(\epsilon) \nabla_{\phi} \log p(\mathbf{x}|g(\mathbf{x}, \epsilon, \phi), \theta) d\epsilon - \nabla_{\phi} \mathsf{KL}(q(\mathbf{z}|\mathbf{x}, \phi)||p(\mathbf{z}))$$

$$\approx \nabla_{\phi} \log p(\mathbf{x}|g(\mathbf{x}, \epsilon^*, \phi), \theta) - \nabla_{\phi} \mathsf{KL}(q(\mathbf{z}|\mathbf{x}, \phi)||p(\mathbf{z}))$$

Variational assumption

$$egin{aligned} r(\epsilon) &= \mathcal{N}(\mathbf{0}, \mathbf{I}); \quad q(\mathbf{z}|\mathbf{x}, \phi) = \mathcal{N}(oldsymbol{\mu}_{\phi}(\mathbf{x}), \sigma_{\phi}^2(\mathbf{x})). \ \mathbf{z} &= g(\mathbf{x}, \epsilon, \phi) = \sigma_{\phi}(\mathbf{x}) \cdot \epsilon + oldsymbol{\mu}_{\phi}(\mathbf{x}). \end{aligned}$$

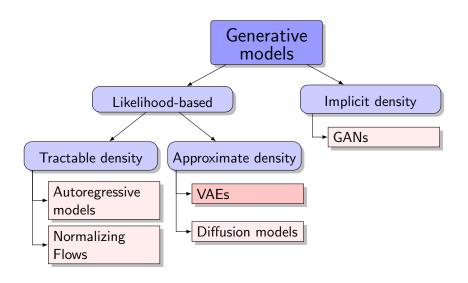

Here $\mu_{\phi}(\cdot)$, $\sigma_{\phi}(\cdot)$ are parameterized functions (outputs of neural network).

- p(z) prior distribution on latent variables z. We could specify any distribution that we want. Let say $p(z) = \mathcal{N}(0, \mathbf{I})$.
- $p(\mathbf{x}|\mathbf{z}, \theta)$ generative distibution. Since it is a parameterized function let it be neural network with parameters θ .

Outline

- 1. EM-algorithm, amortized inference
- ELBO gradients, reparametrization trick
- 3. Variational autoencoder (VAE)

Generative models zoo

Variational autoencoder (VAE)

Final EM-algorithm

- ▶ pick random sample \mathbf{x}_i , $i \sim U[1, n]$.
- compute the objective:

$$egin{aligned} oldsymbol{\epsilon}^* &\sim r(oldsymbol{\epsilon}); \quad \mathbf{z}^* = g(\mathbf{x}, oldsymbol{\epsilon}^*, \phi); \ & \mathcal{L}(\phi, oldsymbol{\theta}) pprox \log p(\mathbf{x}|\mathbf{z}^*, oldsymbol{\theta}) - \mathit{KL}(q(\mathbf{z}^*|\mathbf{x}, \phi)||p(\mathbf{z}^*)). \end{aligned}$$

lacktriangle compute a stochastic gradients w.r.t. ϕ and heta

$$abla_{\phi} \mathcal{L}(\phi, \theta) pprox
abla_{\phi} \log p(\mathbf{x}|g(\mathbf{x}, \epsilon^*, \phi), \theta) -
abla_{\phi} \mathsf{KL}(q(\mathbf{z}|\mathbf{x}, \phi)||p(\mathbf{z}));$$

$$abla_{\theta} \mathcal{L}(\phi, \theta) pprox
abla_{\theta} \log p(\mathbf{x}|\mathbf{z}^*, \theta).$$

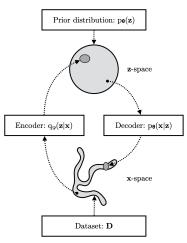

• update θ , ϕ according to the selected optimization method (SGD, Adam, RMSProp):

$$\phi := \phi + \eta \nabla_{\phi} \mathcal{L}(\phi, \theta),$$

$$\theta := \theta + \eta \nabla_{\theta} \mathcal{L}(\phi, \theta).$$

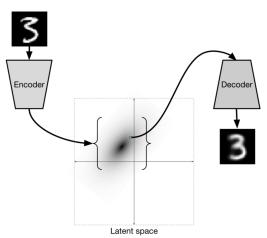

Variational autoencoder (VAE)

- ▶ VAE learns stochastic mapping between **x**-space, from complicated distribution $\pi(\mathbf{x})$, and a latent **z**-space, with simple distribution.
- The generative model learns a joint distribution $p(\mathbf{x}, \mathbf{z}|\boldsymbol{\theta}) = p(\mathbf{z})p(\mathbf{x}|\mathbf{z}, \boldsymbol{\theta})$, with a prior distribution $p(\mathbf{z})$, and a stochastic decoder $p(\mathbf{x}|\mathbf{z}, \boldsymbol{\theta})$.
- The stochastic encoder $q(\mathbf{z}|\mathbf{x}, \phi)$ (inference model), approximates the true but intractable posterior $p(\mathbf{z}|\mathbf{x}, \theta)$ of the generative model.

Variational Autoencoder

$$\mathcal{L}(\phi, oldsymbol{ heta}) = \mathbb{E}_{q(\mathbf{z}|\mathbf{x}, \phi)} \left[\log p(\mathbf{x}|\mathbf{z}, oldsymbol{ heta}) - \log rac{q(\mathbf{z}|\mathbf{x}, \phi)}{p(\mathbf{z})}
ight]
ightarrow \max_{\phi, heta}.$$

Variational autoencoder (VAE)

- lacksquare Encoder $q(\mathbf{z}|\mathbf{x},\phi)=\mathsf{NN}_e(\mathbf{x},\phi)$ outputs $\mu_\phi(\mathbf{x})$ and $\sigma_\phi(\mathbf{x})$.
- ▶ Decoder $p(\mathbf{x}|\mathbf{z}, \boldsymbol{\theta}) = \mathsf{NN}_d(\mathbf{z}, \boldsymbol{\theta})$ outputs parameters of the sample distribution.

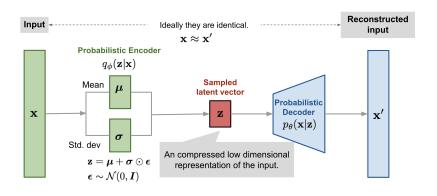

image credit:

VAE limitations

Poor generative distribution (decoder)

$$p(\mathbf{x}|\mathbf{z}, \boldsymbol{\theta}) = \mathcal{N}(\mathbf{x}|\mu_{\boldsymbol{\theta}}(\mathbf{z}), \sigma_{\boldsymbol{\theta}}^2(\mathbf{z})) \quad \text{or } = \mathsf{Softmax}(\pi_{\boldsymbol{\theta}}(\mathbf{z})).$$

Loose lower bound

$$\log p(\mathbf{x}|\boldsymbol{\theta}) - \mathcal{L}(q,\boldsymbol{\theta}) = (?).$$

Poor prior distribution

$$p(\mathbf{z}) = \mathcal{N}(0, \mathbf{I}).$$

Poor variational posterior distribution (encoder)

$$q(\mathsf{z}|\mathsf{x},\phi) = \mathcal{N}(\mathsf{z}|\boldsymbol{\mu}_{\phi}(\mathsf{x}), \sigma_{\phi}^2(\mathsf{x})).$$

VAE as Bayesian model

Posterior distribution

$$p(\theta|\mathbf{X}) = \frac{p(\mathbf{X}|\theta)p(\theta)}{p(\mathbf{X})}$$

ELBO

$$\begin{aligned} \log p(\boldsymbol{\theta}|\mathbf{X}) &= \log p(\mathbf{X}|\boldsymbol{\theta}) + \log p(\boldsymbol{\theta}) - \log p(\mathbf{X}) \\ &= \mathcal{L}(q,\boldsymbol{\theta}) + \mathcal{K}L(q||p) + \log p(\boldsymbol{\theta}) - \log p(\mathbf{X}) \\ &\geq \left[\mathcal{L}(q,\boldsymbol{\theta}) + \log p(\boldsymbol{\theta})\right] - \log p(\mathbf{X}). \end{aligned}$$

EM-algorithm

E-step

$$q(\mathbf{z}) = rg \max_{q} \mathcal{L}(q, \boldsymbol{\theta}^*) = rg \min_{q} \mathit{KL}(q||p) = p(\mathbf{z}|\mathbf{x}, \boldsymbol{\theta}^*);$$

M-step

$$oldsymbol{ heta}^* = rg \max_{oldsymbol{ heta}} \left[\mathcal{L}(q, oldsymbol{ heta}) + \log p(oldsymbol{ heta})
ight].$$

Summary

- The general variational EM algorithm maximizes ELBO objective.
- Amortized variational inference allows to efficiently compute the stochastic gradients for ELBO using Monte-Carlo estimation.
- ► The reparametrization trick gets unbiased gradients w.r.t to the variational posterior distribution.
- ► The VAE model is an LVM with two neural network: stochastic encoder $q(\mathbf{z}|\mathbf{x}, \phi)$ and stochastic decoder $p(\mathbf{x}|\mathbf{z}, \theta)$.
- Standart VAE has several limitations that we will address later in the course.
- ightharpoonup VAE is not a "true" bayesian model since parameters heta do not have a prior distribution.
